

Mathematical and Logical Operations on a Digital Image

Lec-14

By

Lecturer Dr. Omar F. Mohammad

Mathematical Operations on a Digital Image

- 1) **Addition** : is used to combine the information in two images. Applications include development of image restoration algorithm for molding additive noise, and special effects, such as image morphing in motion pictures.

Mathematical Operations on a Digital Image

Since the colors have a value ranging from (0 255), there is a problem when adding two values and the result is more than 255, so it works to cut the colors to 255 because **the type of image 8-bits**, which leads to the **loss of some colors**, so it is preferable **to expand the color field from (0-512)**, i.e. converting the image type into a **16-bits type**

Also, a **fixed number** can be added to the image for the purpose of **lightening** the image

2) **Subtraction:** of two images is often used to **detect motion**, consider the case where nothing has changed in a sense ;the image resulting from subtraction of two sequential image is filled with zero-a black image .If something has moved in the scene, subtraction produces a nonzero result at the location of movement. Applications include **Object tracking, Medical imaging, Law enforcement and Military applications.**

3,4) Multiplication and Division are used to adjust the brightness of an image. One image typically consists of a constant number greater than one. Multiplication of the pixel values by a number greater than one will darken the image (Brightness adjustment is often used as a processing step in image enhancement)

Logical Operations on a Digital Image

Logical operations : apply only to binary images ,whereas arithmetic operations apply to multi-valued pixels. Logical operations are basic tools in binary image processing, where they are used for tasks such as **masking, feature detection ,and shape analysis** .Logical operations on entire image are performed pixel-by-pixel .

Logical **AND & OR** operations are useful for the **masking** and **compositing** of images. For example ,if we compute the AND of a binary image with some other image, then pixels for which the corresponding value in the binary image is **1** will be **preserved**, but pixels for which the corresponding binary value is **0** will be set to **0(erased)**.Thus the binary image acts as a“ mask ”that removes information from certain parts of the image.

Logical operations on a digital image

On the other hand ,if we compute the **OR** of a binary image with some other image, the pixels for which the corresponding value in the binary image is **0** will be **preserved** ,but pixels for which the corresponding binary value is **1**, will be set to **1** (**cleared**.) So ,masking is a simple method to extract a region of interest (ROI) from an image

Logical operations on a digital image

1. AND operation

This operation can be used to find the **similarity** **white** **regions** of two different images (it required two images)
